

Time Series Analysis and Forecasting

Seminar 3: ARIMA Models

Daniel Traian PELE

Bucharest University of Economic Studies

IDA Institute Digital Assets

Blockchain Research Center

AI4EFIN – Artificial Intelligence for Energy Finance

Romanian Academy, Institute for Economic Forecasting

MSCA Digital Finance

Seminar Outline

Today's Activities:

- 1. Review Quiz** — Checking understanding of ARIMA concepts
- 2. True/False Questions** — Conceptual checks
- 3. Practice Problems** — Calculations with ARIMA
- 4. Worked Examples** — Real-world applications
- 5. Real Data Analysis** — GDP case study
- 6. AI Exercises** — Human vs. AI modeling

Quiz 1: Integration Order

Question

A time series Y_t requires two differences to become stationary. What is its order of integration?

Answer choices

- (A) $I(0)$
- (B) $I(1)$
- (C) $I(2)$
- (D) Cannot be determined

Quiz 1: Integration Order

Question

A time series Y_t requires two differences to become stationary. What is its order of integration?

Answer: C – I(2)

Definition: $Y_t \sim I(d)$ if $\Delta^d Y_t$ is stationary but $\Delta^{d-1} Y_t$ is not.

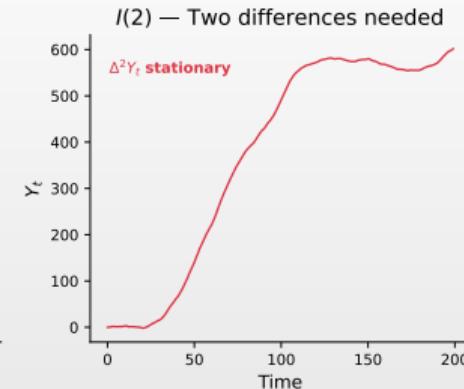

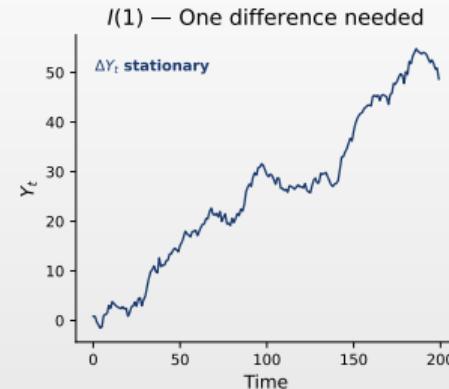

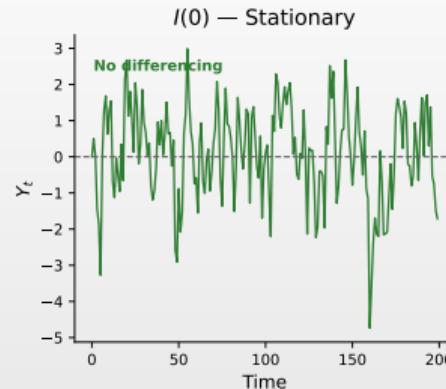

Example: If Y_t follows $\Delta^2 Y_t = \varepsilon_t$, then:

- $\Delta Y_t = \Delta Y_{t-1} + \varepsilon_t$ (still has unit root)
- $\Delta^2 Y_t = \varepsilon_t$ (white noise, stationary)

Real-world: Price levels may be $I(2)$ when inflation itself is non-stationary.

Visual: Integrated Processes

$I(0)$: stationary. $I(1)$: one difference needed. $I(2)$: two differences needed to become stationary.

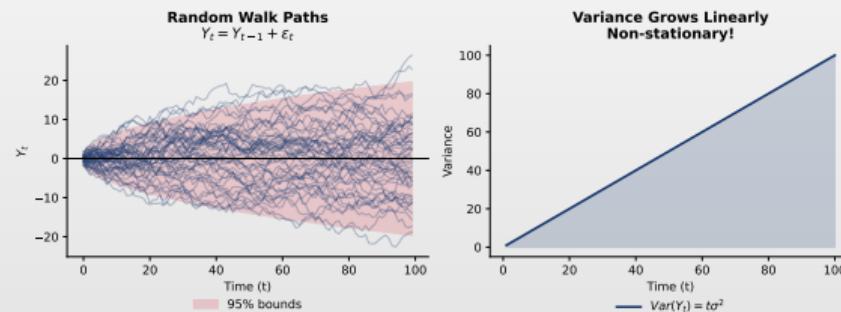

Q TSA_ch3_def_integrated

Quiz 2: Random Walk Properties

Question

For a random walk $Y_t = Y_{t-1} + \varepsilon_t$ with $\text{Var}(\varepsilon_t) = \sigma^2$, what is $\text{Var}(Y_t)$?

Q TSA_ch3_rw_variance

Quiz 3: ADF Test Specification

Question

When applying the ADF test to GDP data (which shows a clear upward trend), what specification should be used?

Answer choices

- (A) No constant, no trend
- (B) With constant, no trend
- (C) With constant and trend
- (D) The specification does not matter

Quiz 3: ADF Test Specification

Question

When applying the ADF test to GDP data (which shows a clear upward trend), what specification should be used?

Answer: C – With constant and trend

ADF regression with trend: $\Delta Y_t = \alpha + \beta t + \gamma Y_{t-1} + \sum \delta_j \Delta Y_{t-j} + \varepsilon_t$

Practical rule:

- No constant:** series with zero mean (rarely used)
- With constant:** series with non-zero mean but no visible trend
- With constant + trend:** series with visible deterministic trend (GDP, prices)

Warning: Wrong specification reduces the power of the test!

Quiz 4: ARIMA Notation

Question

What does ARIMA(2,1,1) mean?

Answer choices

- (A) AR(2) on differenced data with MA(1) errors
- (B) AR(1) with 2 differences and MA(1)
- (C) MA(2) with 1 difference and AR(1)
- (D) 2 lags, 1 trend, 1 seasonal component

Quiz 4: ARIMA Notation

Question

What does ARIMA(2,1,1) mean?

Answer: A – AR(2) on differenced data with MA(1) errors

ARIMA(p, d, q): $\phi(L)(1 - L)^d Y_t = \theta(L)\varepsilon_t$

ARIMA(2,1,1) expands to:

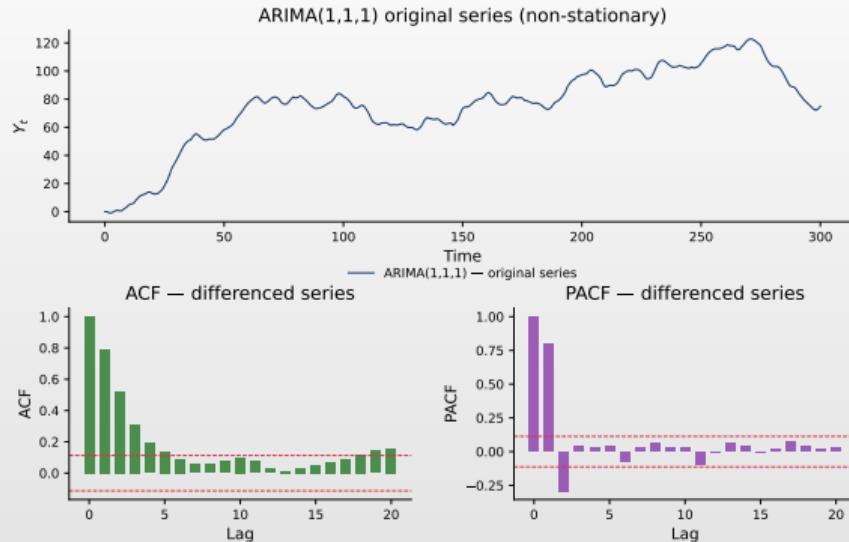

$$(1 - \phi_1 L - \phi_2 L^2)(1 - L)Y_t = (1 + \theta_1 L)\varepsilon_t$$

Or equivalently: $(1 - \phi_1 L - \phi_2 L^2)\Delta Y_t = (1 + \theta_1 L)\varepsilon_t$

Interpretation: First difference the series, then fit ARMA(2,1) to ΔY_t .

Visual: ARIMA Process

Top: original ARIMA series. Bottom: after differencing, use ACF/PACF to identify AR and MA orders.

Q TSA_ch3_def_arima

Quiz 5: ARIMA Equivalence

Question

The ARIMA(0,1,1) model without a constant, $(1 - L)Y_t = (1 + \theta L)\varepsilon_t$, is equivalent to:

Answer choices

- (A) Simple Exponential Smoothing (SES)
- (B) A stationary AR(1) model
- (C) A pure random walk
- (D) A stationary MA(1) model

Quiz 5: ARIMA Equivalence

Question

The ARIMA(0,1,1) model without a constant, $(1 - L)Y_t = (1 + \theta L)\varepsilon_t$, is equivalent to:

Answer: A – Simple Exponential Smoothing (SES)

ARIMA(0,1,1): $Y_t = Y_{t-1} + \varepsilon_t + \theta\varepsilon_{t-1}$

SES: $\hat{Y}_{t+1} = \alpha Y_t + (1 - \alpha) \hat{Y}_t$ with $\alpha = 1 + \theta$

- When $\theta = 0$: pure random walk (naive)
- When $-1 < \theta < 0$: smoothing ($0 < \alpha < 1$)
- The fundamental link between the stochastic and deterministic approaches

Conclusion: SES is the optimal case of an ARIMA(0,1,1)!

Quiz 6: ADF+KPSS Decision Matrix

Question

ADF fails to reject H_0 ($p = 0.15$) and KPSS fails to reject H_0 ($p = 0.08$). What is the conclusion?

Answer choices

- (A) The series is stationary
- (B) The series has a unit root
- (C) Results are inconclusive — insufficient statistical power
- (D) Both tests are wrong

Q TSA_ch3_adf_kpss

Quiz 6: ADF+KPSS Decision Matrix

Question

ADF fails to reject H_0 ($p = 0.15$) and KPSS fails to reject H_0 ($p = 0.08$). What is the conclusion?

Answer: C – Inconclusive results

	ADF fails to rej.	ADF rejects
KPSS fails to rej.	Inconclusive	Stationary
KPSS rejects	Unit root	Inconclusive

Solutions: Larger sample, PP or ERS tests, or sequential procedure — difference and re-test.

Q TSA_ch3_adf_kpss

Quiz 7: Overdifferencing

Question

If $Y_t \sim I(1)$ and we compute $\Delta^2 Y_t$, what happens?

Answer choices

- (A) We get a better stationary series
- (B) We introduce artificial negative autocorrelation
- (C) The variance decreases
- (D) Nothing changes

 TSA_ch3_overdifferencing

Quiz 7: Overdifferencing

Question

If $Y_t \sim I(1)$ and we compute $\Delta^2 Y_t$, what happens?

Answer: B – Artificial negative autocorrelation

Diagnostic: ACF at lag 1 ≈ -0.5 signals overdifferencing. Reduce d by 1!

Q TSA_ch3_overdifferencing

Quiz 8: Forecast Variance

Question

For an ARIMA(0,1,0) model (random walk), how does forecast variance behave as horizon h increases?

Answer choices

- (A) Stays constant
- (B) Decreases to zero
- (C) Grows linearly with h
- (D) Converges to a finite limit

Quiz 8: Forecast Variance

Question

For an ARIMA(0,1,0) model (random walk), how does forecast variance behave as horizon h increases?

Answer: C – Grows linearly with h

Random walk forecast: $\hat{Y}_{T+h|T} = Y_T$ (best forecast is current value)

Forecast error: $Y_{T+h} - \hat{Y}_{T+h|T} = \sum_{i=1}^h \varepsilon_{T+i}$

Variance:

$$\text{Var}(Y_{T+h} - \hat{Y}_{T+h|T}) = h\sigma^2$$

95% CI: $Y_T \pm 1.96\sqrt{h}\sigma$ (widens with \sqrt{h})

Quiz 9: Unit Root Test Power

Question

The ADF test has low power when:

Answer choices

- (A) Sample size is very large
- (B) The true root is close to but not equal to 1
- (C) The series has no trend
- (D) The series is clearly stationary

Quiz 9: Unit Root Test Power

Question

The ADF test has low power when:

Answer: B – Root close to but not equal to 1

Example: AR(1) with $\phi = 0.95$ vs random walk ($\phi = 1$)

Problem: Both have similar ACF patterns (slow decay), but one is stationary!

Low power means: High probability of Type II error (failing to reject false H_0)

Solutions:

- Larger sample sizes
- Phillips-Perron test (robust to heteroskedasticity)
- Panel unit root tests (multiple series)

Quiz 10: ARIMA Model Selection

Question

After differencing once, the ACF shows a spike at lag 1 only, and PACF decays. The appropriate model is:

Answer choices

- (A) ARIMA(1,1,0)
- (B) ARIMA(0,1,1)
- (C) ARIMA(1,1,1)
- (D) ARIMA(0,2,1)

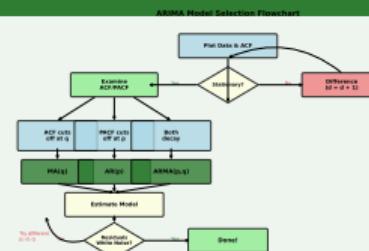

Q TSA_ch3_arima_flowchart

Quiz 10: ARIMA Model Selection

Question

After differencing once, the ACF shows a spike at lag 1 only, and PACF decays. The appropriate model is:

Answer: B – ARIMA(0,1,1)

Pattern: ACF cuts off at lag 1, PACF decays \Rightarrow MA(1) for differenced series. Full model: ARIMA(0,1,1) = IMA(1,1)

Q TSA_ch3_arima_flowchart

Quiz 11: Trend Stationarity vs Difference Stationarity

Question

A trend-stationary process is made stationary by:

Answer choices

- (A) Taking first differences
- (B) Removing the deterministic trend via regression
- (C) Taking second differences
- (D) Applying seasonal adjustment

Q TSA_ch3_trend_vs_diff

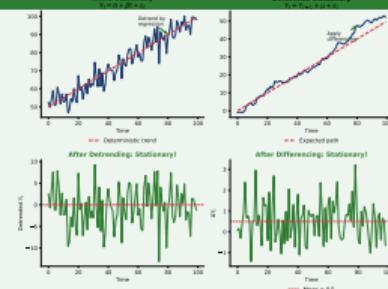

Quiz 11: Trend Stationarity vs Difference Stationarity

Question

A trend-stationary process is made stationary by:

Answer: B – Removing deterministic trend via regression

Trend-stationary: Detrend (shocks are temporary). **Difference-stationary:** Difference (shocks are permanent). Wrong treatment affects the model!

Q TSA_ch3_trend_vs_diff

Quiz 12: ARIMA Invertibility

Question

ARIMA(0,1,1) with $\theta_1 = 1.2$ is:

Answer choices

- (A) Stationary and invertible
- (B) Non-stationary but invertible
- (C) Non-stationary and non-invertible
- (D) Stationary but non-invertible

Quiz 12: ARIMA Invertibility

Question

ARIMA(0,1,1) with $\theta_1 = 1.2$ is:

Answer: C – Non-stationary and non-invertible

Stationarity check: $d = 1$ means a unit root \Rightarrow Non-stationary

Invertibility check: The MA polynomial is $\theta(z) = 1 + 1.2z$

- Root: $z = -1/1.2 = -0.833$ (inside the unit circle)
- Invertibility requires the root outside the unit circle
- $|\theta_1| = 1.2 > 1 \Rightarrow$ Non-invertible

Fix: Rewrite with $\theta^* = 1/1.2 = 0.833$ and adjust variance.

Quiz 13: Spurious Regression

Question

Regressing one random walk on another independent random walk typically shows:

Answer choices

- (A) No significant relationship
- (B) High R^2 and significant t-statistics (spuriously)
- (C) Negative correlation
- (D) Perfect multicollinearity

Quiz 13: Spurious Regression

Question

Regressing one random walk on another independent random walk typically shows:

Answer: B – High R^2 and significant t-statistics (spuriously)

Granger & Newbold (1974): Spurious regression phenomenon

Symptoms:

- High R^2 (often > 0.9) between unrelated series
- Significant t -statistics
- Very low Durbin-Watson statistic ($\ll 2$)
- Non-stationary residuals

Solutions: (1) Difference both series, or (2) Test for cointegration

Quiz 14: Long-Run Forecast

Question

The long-run forecast from ARIMA(1,1,0) with $\phi_1 = 0.7$ converges to:

Answer choices

- (A) Zero
- (B) The unconditional mean
- (C) A linear trend extrapolation
- (D) The last observed value

Quiz 14: Long-Run Forecast

Question

The long-run forecast from ARIMA(1,1,0) with $\phi_1 = 0.7$ converges to:

Answer: C – A linear trend extrapolation

Model: $(1 - \phi_1 L)(1 - L)Y_t = c + \varepsilon_t$

Long-run forecast: For I(1) models with drift c :

$$\hat{Y}_{T+h} \approx Y_T + h \cdot \frac{c}{1 - \phi_1}$$

Key differences:

- Stationary ARMA: Forecasts \rightarrow unconditional mean
- I(1) without drift: Forecasts \rightarrow last value (flat)
- I(1) with drift: Forecasts \rightarrow linear extrapolation

True/False Questions

Question

Determine if each statement is True or False:

1. An I(2) process requires two differences to become stationary.
2. The ADF test always includes a constant term.
3. ARIMA(0,1,0) is another name for a random walk.
4. Differencing a stationary series makes it “more stationary.”
5. The KPSS test has stationarity as the null hypothesis.
6. ARIMA models can only capture linear patterns.

Answer on next slide...

True/False: Solutions

Answers

- | | |
|--|--|
| 1. $I(2)$ requires two differences. | TRUE d differences for $I(d)$. $I(2) =$ two unit roots. |
| 2. The ADF test always includes a constant term. | FALSE You choose: no constant, constant only, or constant + trend. |
| 3. ARIMA(0,1,0) = random walk. | TRUE $(1 - L)Y_t = \varepsilon_t \Rightarrow Y_t = Y_{t-1} + \varepsilon_t$. |
| 4. Differencing a stationary series \rightarrow “more stationary.” | FALSE Over-differencing creates non-invertible MA. |
| 5. KPSS: H_0 = stationary. | TRUE Opposite of ADF (H_0 = unit root). |
| 6. ARIMA captures only linear patterns. | TRUE Linear in parameters. Nonlinear \rightarrow GARCH, neural nets. |

Problem 1: Unit Root Testing

Exercise

You have quarterly GDP data for 80 quarters. The ADF test (with constant and trend) gives a test statistic of -2.85 . The 5% critical value is -3.41 .

1. What is your conclusion about stationarity?
2. What would you do next?

Problem 1: Unit Root Testing

Exercise

You have quarterly GDP data for 80 quarters. The ADF test (with constant and trend) gives a test statistic of -2.85 . The 5% critical value is -3.41 .

1. What is your conclusion about stationarity?
2. What would you do next?

Solution

1. Since $-2.85 > -3.41$, we **fail to reject H_0** . The data appears to have a unit root (non-stationary).
2. Take the first difference ΔY_t and repeat the ADF test on the differenced series to confirm it is now stationary.

Problem 2: Model Identification

Exercise

After differencing a time series once, the ACF shows:

- Significant spike at lag 1 ($\rho_1 = 0.4$)
- All other lags insignificant

The PACF shows gradual decay.

What ARIMA model is suggested?

Problem 2: Model Identification

Exercise

After differencing a time series once, the ACF shows:

- Significant spike at lag 1 ($\rho_1 = 0.4$)
- All other lags insignificant

The PACF shows gradual decay.

What ARIMA model is suggested?

Solution

- ACF cuts off after lag 1 \Rightarrow MA(1) component
- PACF decays \Rightarrow Confirms MA structure
- Since we differenced once: $d = 1$

Suggested model: ARIMA(0,1,1) or IMA(1,1)

Problem 3: ARIMA Equation

Exercise

Write out the full equation for ARIMA(1,1,1):

$$(1 - \phi_1 L)(1 - L)Y_t = c + (1 + \theta_1 L)\varepsilon_t$$

Expand this completely in terms of Y_t , Y_{t-1} , Y_{t-2} , etc.

Problem 3: ARIMA Equation

Exercise

Write out the full equation for ARIMA(1,1,1):

$$(1 - \phi_1 L)(1 - L)Y_t = c + (1 + \theta_1 L)\varepsilon_t$$

Expand this completely in terms of Y_t , Y_{t-1} , Y_{t-2} , etc.

Solution

Expanding $(1 - \phi_1 L)(1 - L) = 1 - L - \phi_1 L + \phi_1 L^2 = 1 - (1 + \phi_1)L + \phi_1 L^2$:

$$Y_t - (1 + \phi_1)Y_{t-1} + \phi_1 Y_{t-2} = c + \varepsilon_t + \theta_1 \varepsilon_{t-1}$$

Or equivalently:

$$Y_t = c + (1 + \phi_1)Y_{t-1} - \phi_1 Y_{t-2} + \varepsilon_t + \theta_1 \varepsilon_{t-1}$$

Problem 4: Forecast Calculation

Exercise

Given ARIMA(0,1,1): $\Delta Y_t = \varepsilon_t + 0.3\varepsilon_{t-1}$

At time T : $Y_T = 100$, $\hat{\varepsilon}_T = 2$, $\sigma^2 = 4$

Calculate:

1. $\hat{Y}_{T+1|T}$ (one-step forecast)
2. $\hat{Y}_{T+2|T}$ (two-step forecast)

Problem 4: Forecast Calculation

Exercise

Given ARIMA(0,1,1): $\Delta Y_t = \varepsilon_t + 0.3\varepsilon_{t-1}$

At time T : $Y_T = 100$, $\hat{\varepsilon}_T = 2$, $\sigma^2 = 4$

Calculate:

1. $\hat{Y}_{T+1|T}$ (one-step forecast)
2. $\hat{Y}_{T+2|T}$ (two-step forecast)

Solution

$$1. \hat{Y}_{T+1|T} = Y_T + 0.3\hat{\varepsilon}_T = 100 + 0.3(2) = 100.6$$

$$2. \hat{Y}_{T+2|T} = \hat{Y}_{T+1|T} + 0.3 \cdot 0 = 100.6 + 0 = 100.6$$

(Future shocks $\varepsilon_{T+1}, \varepsilon_{T+2}$ are forecast as 0)

Problem 5: Confidence Intervals

Exercise

Continuing from Problem 4, calculate the 95% forecast intervals for $\hat{Y}_{T+1|T}$ and $\hat{Y}_{T+2|T}$.
Recall: $\sigma^2 = 4$, $\theta_1 = 0.3$

Problem 5: Confidence Intervals

Exercise

Continuing from Problem 4, calculate the 95% forecast intervals for $\hat{Y}_{T+1|T}$ and $\hat{Y}_{T+2|T}$.
Recall: $\sigma^2 = 4$, $\theta_1 = 0.3$

Solution

For IMA(1,1), the MA(∞) weights are $\psi_0 = 1$, $\psi_j = 1 + \theta_1$ for $j \geq 1$.

1-step: $\text{Var}(e_{T+1}) = \sigma^2 \psi_0^2 = 4$, so $SE = 2$

$$100.6 \pm 1.96(2) = [96.68, 104.52]$$

2-step: $\text{Var}(e_{T+2}) = \sigma^2(\psi_0^2 + \psi_1^2) = 4(1 + 1.3^2) = 10.76$, $SE = 3.28$

$$100.6 \pm 1.96(3.28) = [94.17, 107.03]$$

Example: Testing for Unit Root in Stock Prices

Scenario

You have daily closing prices for a stock over 500 days. You want to determine if prices follow a random walk.

Step-by-step Approach

1. **Visual inspection:** Plot prices – likely shows trend
2. **ADF test on prices:** Expect to fail to reject H_0 (unit root)
3. **Take log returns:** $r_t = \ln(P_t/P_{t-1}) = \Delta \ln(P_t)$
4. **ADF test on returns:** Should reject H_0 (stationary)
5. **Conclusion:** Log prices are $I(1)$, returns are $I(0)$

Example: Box-Jenkins for Inflation Data

Scenario

Monthly inflation rates for 10 years. Build an ARIMA model.

Workflow

1. **Plot & test:** ADF suggests borderline – try both $d = 0$ and $d = 1$
2. **If $d = 0$:** Fit ARMA models, compare AIC
3. **If $d = 1$:** Examine ACF/PACF of ΔY_t
 - ▶ ACF: spike at lag 1, then cuts off
 - ▶ PACF: decays
 - ▶ ⇒ Try ARIMA(0,1,1)
4. **Estimate:** Fit ARIMA(0,1,1), check coefficients
5. **Diagnose:** Ljung-Box on residuals (want $p > 0.05$)
6. **Compare:** AIC of ARIMA(0,1,1) vs ARMA(1,1) on levels

Example: Interpreting Python Output

statsmodels ARIMA Output

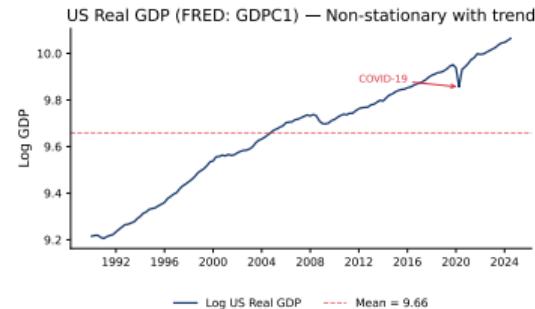

```
ARIMA Model Results
=====
Dep. Variable:      D.y    No. Observations:     99
Model:             ARIMA(1,1,1)    AIC:            285.32
                  BIC:            295.63
=====
                           coef    std err        z     P>|z|
-----
const            0.0521    0.048     1.085    0.278
ar.L1            0.4532    0.102     4.443    0.000
ma.L1           -0.2891    0.118    -2.450    0.014
sigma2          1.2340    0.176     7.011    0.000
```

Interpretation

- AR (0.45) significant, MA (-0.29) significant
- Constant (0.052) not significant – could set $c = 0$
- Check: $|\phi_1| < 1$ (stationary), $|\theta_1| < 1$ (invertible) – OK!

Case Study: US Real GDP (1990–2024)

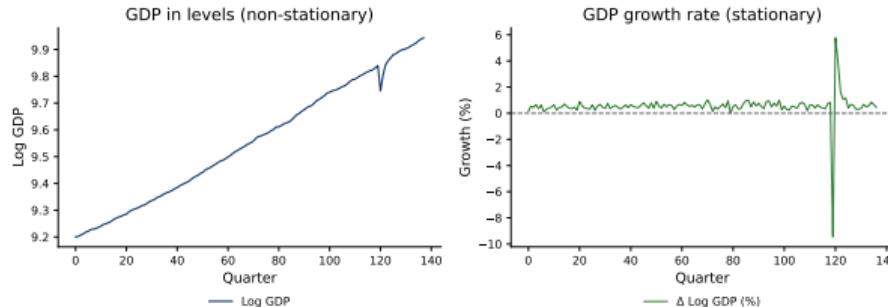

Observations

US Real GDP in billions of 2017 dollars (quarterly). Clear **upward trend**. Drops during recessions (2008–09, 2020). Non-stationary: needs differencing.

Q TSA_ch3_gdp_levels

Stationarity Through Differencing

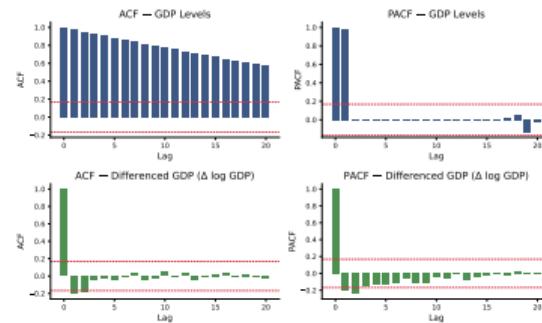

Observations

- Left: GDP in levels — clear upward trend (non-stationary)
- Right: GDP growth rate = $\Delta \log(Y_t) \times 100$ — stationary, fluctuates around mean ($\approx 0.6\%/\text{quarter}$)

TSA_ch3_differencing

ACF/PACF: Levels vs Differenced

Observations

- Top row: ACF/PACF of GDP levels — slow decay \Rightarrow non-stationarity
- Bottom row: ACF/PACF of GDP growth — values within confidence bands
- A low-order ARIMA model is appropriate

Q TSA_ch3_acf_pacf

ARIMA Estimation Results: US GDP Growth

Model: ARIMA(1, 1, 1) on log(GDP)

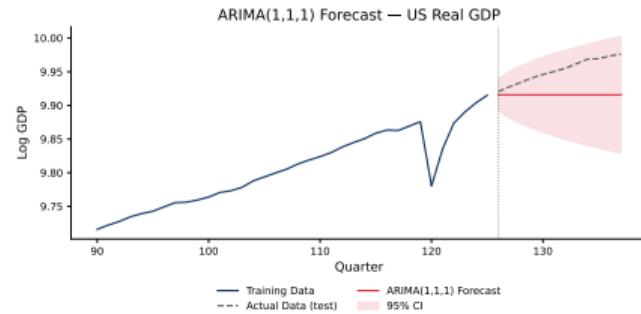

Parameter	Estimate	Std. Error	z-stat	p-value
ϕ_1 (AR.L1)	0.312	0.185	1.69	0.091
θ_1 (MA.L1)	-0.087	0.203	-0.43	0.668
σ^2	0.00012	-	-	-

Interpretation

- Low-order ARIMA captures GDP dynamics reasonably well
- AR(1) coefficient positive – GDP growth shows persistence
- Alternative: simpler random walk (ARIMA(0,1,0)) often competitive

Forecast: ARIMA vs Actual

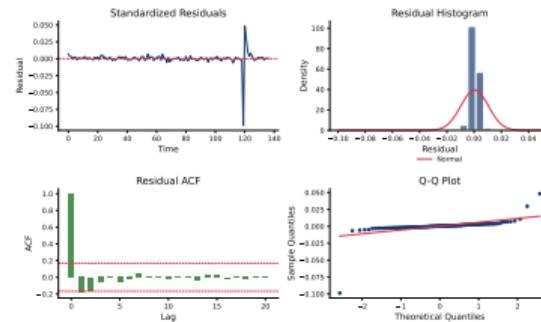

Observations

- Blue: historical training data; Green: actual test data
- Red: ARIMA forecasts with 95% CI — CI widens with forecast horizon

 TSA_ch3_arima_forecast

Model Diagnostics: Residual Analysis

Observations

- Residuals without systematic patterns over time; approximately normal distribution (histogram, Q-Q)
- ACF of residuals within bounds — no autocorrelation; model adequately captures the data generating process

Discussion: Deterministic vs Stochastic Trends

Key Question

Why is it important to distinguish between deterministic and stochastic trends?

Discussion Points

- Wrong treatment consequences:**
 - ▶ Detrending a unit root \Rightarrow spurious stationarity
 - ▶ Differencing a trend-stationary \Rightarrow overdifferencing
- Economic interpretation:**
 - ▶ Deterministic trend: shocks are temporary
 - ▶ Stochastic trend: shocks have permanent effects
- Policy implications:**
 - ▶ Does a recession permanently lower GDP, or does the economy return to trend?

Discussion: Model Selection Criteria

Key Question

When should you use AIC vs BIC for ARIMA model selection?

Considerations

- AIC:** Minimizes prediction error, may overfit
 - ▶ Better for forecasting
 - ▶ Tends to select larger models
- BIC:** Consistent model selection, more parsimonious
 - ▶ Better for identifying “true” model
 - ▶ Penalizes complexity more heavily
- Practical advice:** Report both, prefer BIC if they disagree substantially

Discussion: Limitations of ARIMA

Key Question

What are the main limitations of ARIMA models?

Discussion Points

- Linearity:** Cannot capture nonlinear dynamics
- Constant variance:** Assumes homoskedasticity (no GARCH)
- No structural breaks:** Parameters assumed constant
- Univariate:** Ignores relationships with other variables
- Symmetric:** Treats positive and negative shocks equally
- Long-horizon forecasts:** Uncertainty grows rapidly

Extensions

These limitations motivate GARCH (volatility), VAR (multivariate), regime-switching models, etc.

AI Exercise 1: Critique an AI ARIMA Analysis

Scenario

You asked an AI: "Fit the best ARIMA model to this GDP data." It returned:

- Fitted ARIMA(3,2,3) with AIC = 1542.7
- No ADF test performed
- Ljung-Box p-value = 0.02 (reported as "acceptable")
- 30-year forecast with narrow confidence intervals

Your critique:

1. Is ARIMA(3,2,3) over-parameterized? What would BIC suggest?
2. Why is Ljung-Box $p = 0.02$ **not** acceptable at the 5% level?
3. Are 30-year forecasts reliable for ARIMA models? Why?
4. What steps from the Box-Jenkins methodology were skipped?

AI Exercise 2: Prompt Refinement for ARIMA

Task

Iteratively improve prompts for fitting an ARIMA model to GDP data.

Round 1 (vague): “*Fit a time series model to GDP*”

- What did the AI produce? What is missing?

Round 2 (better): “*Test stationarity with ADF and KPSS, difference if needed, examine ACF/PACF, fit ARIMA(p,d,q) using BIC, check residuals with Ljung-Box*”

- Did the AI follow the Box-Jenkins methodology?

Round 3 (expert): “*Follow Box-Jenkins: (1) plot & test stationarity ADF+KPSS, (2) differencing, (3) identify orders from ACF/PACF, (4) estimate ARIMA(1,1,1), (5) Ljung-Box on residuals, (6) forecast 8 quarters with 95% CI*”

- Compare results across all three rounds

AI Exercise 3: Model Selection Competition

Task

Download quarterly US Real GDP data from FRED (series GDPC1).

Your approach (manual):

- ADF + KPSS tests → differencing
- ACF/PACF → candidate models
- AIC/BIC: ARIMA(0,1,0), (1,1,0), (0,1,1), (1,1,1)
- Residual diagnostics + rolling 1-step forecast

AI approach:

- Ask the AI: "find the best ARIMA and make forecasts"

Compare:

- What model did each select? Compare RMSE
- Rolling vs multi-step forecasts?
- Submit:** 1-page reflection on AI

Key Formulas Summary

Concept	Formula
Random walk	$Y_t = Y_{t-1} + \varepsilon_t$
Random walk variance	$\text{Var}(Y_t) = t\sigma^2$
ARIMA(p, d, q)	$\phi(L)(1 - L)^d Y_t = \theta(L)\varepsilon_t$
First difference	$\Delta Y_t = Y_t - Y_{t-1} = (1 - L)Y_t$
Second difference	$\Delta^2 Y_t = Y_t - 2Y_{t-1} + Y_{t-2}$
ADF regression	$\Delta Y_t = \alpha + \gamma Y_{t-1} + \sum \delta_j \Delta Y_{t-j} + \varepsilon_t$
ADF null	$H_0 : \gamma = 0$ (unit root)
RW forecast	$\hat{Y}_{T+h T} = Y_T$
RW forecast CI	$Y_T \pm z_{\alpha/2} \sqrt{h} \sigma$
AIC	$-2 \ln(\hat{L}) + 2k$
BIC	$-2 \ln(\hat{L}) + k \ln(n)$

Notation: \hat{L} = maximum of the likelihood function, k = no. of parameters, n = sample size, σ^2 = white noise variance

Thank You!
